The physical origins of constitutive, as opposed to stress-induced, growth are investigated by proposing a simple cell design that exhibits constitutive growth at the single-cell level. At the macroscopic level, this system exhibits a switch-like response to changes in extracellular nutrients. The single-cell, physical insights gained with this system are then extended to study how these insights translate into effects at the cellular level. As a physical representation of a cell, the model

describes growth as the irreversible accumulation of cell mass (that is, cells grow without division or depletion of the available nutrient). The model is then analyzed in a quantitative, mathematical framework to analyze the growth of a single, well-stirred, cell. The analysis yields three basic results: (1) a quantitative physical interpretation of the growth kinetics of individual cells, (2) a quantitative definition of a
