However, the pressure gradients, which is proportional to q_m , as opposed to the particle fluxes which are proportional to p_m , are now expected to be much smaller than in the case of the Legendre polynomials. The reduction of the pressure gradient with the distance from the wall due to a finite-size, compared to the case of the Legendre polynomials, is shown in Fig.  (Color online) Integral-pressure profile $\langle \Pi_m \rangle$, plotted versus the distance from the wall z , for different widths of the spherical particle and different reference points in the simulation box.  From Fig.  it is clear that, due to the spherical symmetry of the particle, the integral pressure is independent of z , which implies that the pressure-gradient contribution to the transport is absent and thus one expects a vanishing particle flux. Hence, it is not surprising that the particle flux becomes negligible as the size of the spherical particle becomes large. [100] ca3bf1094
